

Work

- Consider the compression of a gas

$$dW = F \cdot dx$$

$$\text{now } A dx = -dV$$

So since  $p = F/A$  we have

$$dW = -p(T, V) dV$$

work by me

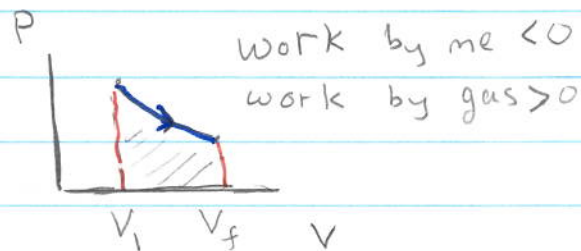

determined by EOS  $\beta_P, K_T$

- This is the work by me on gas. Of course, the work by the gas on me is minus this,  $dW_{\text{by gas}} = +p dV$ .

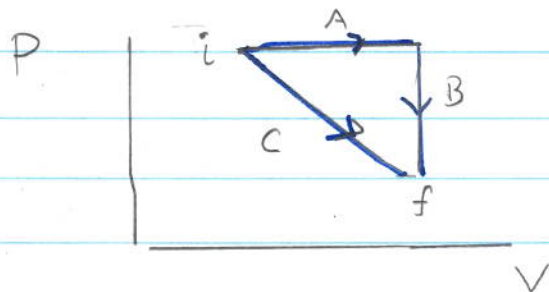

- So

$$W_{if} = - \int_i^f p(T, V) dV$$

= - Area under curve

- The work done depends on the path e.g.

- i.e. the work  $W_A + W_B \neq W_C$

We say  $\delta W$  is an inexact differential. Meaning it represents a small amount of work,  $dV$  is an exact differential and represents a small change in volume  $V$ ,  $dV = V_f - V_i$ , it does not depend on the path

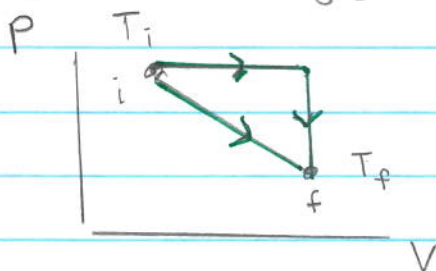

## The First Law

- The change in energy of the system is the heat put in and the work done

$$dU = \delta Q + \delta W$$

$\nearrow$   $\uparrow$   $\nwarrow$   
 Change in energy    amount of heat put in    amount of work done

- The change in energy is independent of the path

- At the initial and final points the temperature is determined by the eos  $P = P(T, V)$

And  $\Delta U = U_f - U_i$

with e.g.  $U_f = U(T_f, V_f)$

## Heat Capacity + The First Law

- Consider the energy of the system  $U(T, V)$  as a function of volume of the gas and temperature. The number of particles is held fixed (implicitly):

$$dU = \left( \frac{\partial U}{\partial T} \right)_V dT + \left( \frac{\partial U}{\partial V} \right)_T dV \quad \sim \text{kinetic and potential terms}$$

So the heat that flows in is:

$$dQ = dU - dW \quad (\text{use } dW = -pdV)$$

$$dQ = \left( \frac{\partial U}{\partial T} \right)_V dT + \left[ \left( \frac{\partial U}{\partial V} \right)_T + P \right] dV$$

① So first if volume is held constant:

$$dQ_V = \left( \frac{\partial U}{\partial T} \right)_V dT_V$$

$$C_V = \left( \frac{dQ_V}{dT} \right)_V = \left( \frac{\partial U}{\partial T} \right)_V$$

we quoted this earlier

So a specific heat measurement tells you about the internal energy changes

So for a MAIG

$$U = \frac{3}{2} N k_B T \quad \text{and} \quad C_V = \frac{3}{2} N k_B$$

② Now if pressure is held fixed

$$\star \quad C_p = \left( \frac{dQ}{dT} \right)_p = C_V + \left[ \left( \frac{\partial U}{\partial V} \right)_T + p \right] \left( \frac{dV}{dT} \right)_p$$

Now recall

$$\uparrow V \beta_p$$

$$\frac{1}{V} \left( \frac{dV}{dT} \right)_p \equiv \beta_p \equiv \text{thermal expansion coefficient}$$

• Remark Eq.  $\star$  after small algebra gives

$$\left( \frac{\partial U}{\partial V} \right)_T = \frac{C_p - C_V}{V \beta_p} - p$$

So this gives us an experimental way to determine  $\left( \frac{\partial U}{\partial V} \right)_T$ . Recall that  $\left( \frac{\partial U}{\partial V} \right)_T$  reflects the interactions between

the particles, which is reflected in the energy response  $C_p, C_V$  and the expansion,  $\beta_p$ .

• Ideal Gasses have  $\left( \frac{\partial U}{\partial V} \right)_T = 0$ ,

$$\text{and, } V = \frac{N k_B T}{p} \Rightarrow \left( \frac{\partial V}{\partial T} \right)_p = \frac{N k_B}{p}$$

and so we find as claimed earlier

$$C_p = C_v + N k_B$$

(ideal gas)

- For ideal mono-atomic / diatomic gasses  $C_v$  is  $\frac{3}{2} k_B T$  or  $\frac{5}{2} k_B T$  respectively and  $C_p$  is.

$$C_p = \begin{cases} \frac{5}{2} N k_B & (\text{mono}) \\ \frac{7}{2} N k_B & (\text{dia}) \end{cases} \quad \text{or} \quad C_p^{\text{mole}} = \begin{cases} \frac{5}{2} R \\ \frac{7}{2} R \end{cases}$$

↑  
cp per mole

- For later use we define

$$\gamma \equiv \frac{C_p}{C_v} = \frac{C_v + N k_B}{C_v}$$

this is called the  
adiabatic index  
because it arises

For a MAIG we have

in an adiabatic expansion

$$\gamma = \frac{\frac{3}{2} N k_B + N k_B}{\frac{3}{2} N k_B} = \frac{5}{3}$$
